

hover.nvim handbook

Rest the cursor on something that points somewhere, and a float shows what it points at.

1. What hovers

A markdown link, a bare path in prose, a file.md#heading anchor, an image, a PDF, a video, an office document, an http(s) URL. Each target type has a switch; each switch has a command (:Hover auto <type>, :Hover links web on, ...).

2. What a float can hold

Text is always there. A picture needs images.nvim and a terminal with a graphics protocol (kitty, sixel). A PDF page is rendered by pdfport.nvim, a video frame by media.nvim; without a graphics terminal the float says what it knows instead: type, size, resolution, length, page count.

3. When nothing hovers

:Hover why names the gate that refused -- the mode, a switch, a source that did not claim the position -- and what to type about it.

4. Around it

markdown.nvim contributes the link scanner. images.nvim draws. pdfport.nvim and media.nvim render pages and frames. All of them are soft: without them, everything else works unchanged. lib.nvim is the one real dependency.
